I've only seen examples where it's used in place of a "magic number" but I don't see the point in just giving that value to a variable instead. Assign pandas dataframe column dtypes - Stack Overflow I want to set the dtypes of multiple columns in pd.DataFrame (I have a file that I've had to manually parse into a list of lists, as the file was not amenable for pd.read\_csv) import pandas as pd ... Creating an empty Pandas DataFrame, and then filling it NEVER grow a DataFrame row-wise! TLDR: (just read the bold text) Most answers here will tell you how to create an empty DataFrame and fill it out, but no one will tell you that it is a bad thing to do. Here is my advice: Accumulate data in a list, not a DataFrame. Use a list to collect your data, then initialise a DataFrame when you are ready. I'm sure there are other possible use cases. Besides, it's normal to give simplified examples when asking theoretical questions. Pointing out there's a different way is kind of pointless for this kind of question. *c++ - What does ## in a #define mean? - Stack Overflow* In other words, when the compiler starts building your code, no #define statements or anything like that is left. A good way to understand what the preprocessor does to your code is to get hold of the preprocessed output and look at it. **How do I show the value of a #define at compile-time?** I know that this is a long time after the original query, but this may still be useful. This can be done in GCC using the stringify operator "#", but it requires two additional stages to be defined first. `#define XSTR(x) STR(x) #define STR(x) #x` The value of a macro can then be displayed with: `#pragma message "The value of ABC: " XSTR(ABC)` See: 3.4 Stringification in the gcc online ... **How to declare variable and use it in the same Oracle SQL script?** I want to write reusable code and need to declare some variables at the beginning and reuse them in the script,
